Tensor-based Models of Natural Language Semantics

Dimitri Kartsaklis
Joint work with M. Sadrzadeh (QMUL), B. Coecke (Oxford) and R. Piedeleu (Oxford)

School of Electronic Engineering and Computer Science

Workshop on Tensors, their Decomposition, and Applications
QMUL, 16th August 2016
In a nutshell

- **Tensor-based models of meaning** aim to unify two orthogonal semantic paradigms:
  - The type-logical compositional approach of formal semantics
  - The quantitative perspective of vector space models of meaning

- Useful in every NLP task: sentence similarity, paraphrase detection, sentiment analysis, machine translation etc.

In this talk:

I provide an introduction to the field by presenting the mathematical foundations, discussing important extensions and recent work, and touching implementation issues and practical applications.
1. Distributional Semantics

2. Categorical Compositional Distributional Semantics

3. Creating Relational Tensors

4. Dealing with Functional Words

5. A Quantum Perspective

6. Conclusions and Future Work
Computational linguistics is the scientific and engineering discipline concerned with understanding written and spoken language from a computational perspective.

Distributional models of meaning

- A word is a **vector** of co-occurrence statistics with every other word in a selected subset of the vocabulary:

![Diagram showing vector representation of words with co-occurrence counts]

- Semantic relatedness is usually based on cosine similarity:

\[
\text{sim}(\vec{v}, \vec{u}) = \cos \theta = \frac{\langle \vec{v} \cdot \vec{u} \rangle}{\| \vec{v} \| \| \vec{u} \|}
\]
Moving to phrases and sentences

- We would like to generalize this idea to phrases and sentences
- However, it’s not clear how
- There are practical problems—there is not enough data:

![Example of searching for a natural language term](image)

- But even if we had a very large corpus, what the context of a sentence would be?
Moving to phrases and sentences

- We would like to generalize this idea to phrases and sentences
- However, it’s not clear how
- There are practical problems—there is not enough data:

But even if we had a very large corpus, what the context of a sentence would be?

A solution:

For a sentence $w_1 w_2 \ldots w_n$, find a function $f$ such that:

$$\vec{s} = f(\vec{w}_1, \vec{w}_2, \ldots, \vec{w}_n)$$

Quantizing the grammar

Coecke, Sadrzadeh and Clark (2010):

Pregroup grammars are structurally homomorphic with the category of finite-dimensional vector spaces and linear maps (both share compact closure)

- In abstract terms, there exists a structure-preserving passage from grammar to meaning:

\[ \mathcal{F} : \text{Grammar} \rightarrow \text{Meaning} \]

- The meaning of a sentence \( w_1w_2\ldots w_n \) with grammatical derivation \( \alpha \) is defined as:

\[
\overrightarrow{w_1w_2\ldots w_n} := \mathcal{F}(\alpha)(\overrightarrow{w_1} \otimes \overrightarrow{w_2} \otimes \ldots \otimes \overrightarrow{w_n})
\]
A pregroup grammar \( P(\Sigma, \mathcal{B}) \) is a relation that assigns grammatical types from a pregroup algebra freely generated over a set of atomic types \( \mathcal{B} \) to words of a vocabulary \( \Sigma \).

- **A pregroup algebra** is a partially ordered monoid, where each element \( p \) has a left and a right adjoint such that:
  \[
  p \cdot p^r \leq 1 \leq p^r \cdot p \quad p^l \cdot p \leq 1 \leq p \cdot p^l
  \]
- Elements of the pregroup are basic (atomic) grammatical types, e.g. \( \mathcal{B} = \{n, s\} \).
- Atomic grammatical types can be combined to form types of higher order (e.g. \( n \cdot n^l \) or \( n^r \cdot s \cdot n^l \))
- A sentence \( w_1 w_2 \ldots w_n \) (with word \( w_i \) to be of type \( t_i \)) is grammatical whenever:
  \[
  t_1 \cdot t_2 \cdot \ldots \cdot t_n \leq s
  \]
Pregroup derivation: example

\[ p \cdot p^r \leq 1 \leq p^r \cdot p \]

\[ p^l \cdot p \leq 1 \leq p \cdot p^l \]

\[ n \cdot n^l \cdot n \cdot n^r \cdot s \cdot n^l \cdot n \leq n \cdot 1 \cdot n^r \cdot s \cdot 1 \]

\[ = n \cdot n^r \cdot s \]

\[ \leq 1 \cdot s \]

\[ = s \]
A monoidal category \((\mathcal{C}, \otimes, I)\) is **compact closed** when every object has a left and a right adjoint, for which the following morphisms exist:

\[
A \otimes A^r \xrightarrow{\epsilon^r} I \xrightarrow{\eta^r} A^r \otimes A \quad \quad \quad A^l \otimes A \xrightarrow{\epsilon^l} I \xrightarrow{\eta^l} A \otimes A^l
\]

- Pregroup grammars are CCCs, with \(\epsilon\) and \(\eta\) maps corresponding to the partial orders

- **FdVect**, the category of finite-dimensional vector spaces and linear maps, is a also a (symmetric) CCC:
  - \(\epsilon\) maps correspond to inner product
  - \(\eta\) maps to identity maps and multiples of those
We define a strongly monoidal functor $\mathcal{F}$ such that:

$$\mathcal{F} : P(\Sigma, B) \to \text{FdVect}$$

- $\mathcal{F}(p) = P \quad \forall p \in B$
- $\mathcal{F}(1) = \mathbb{R}$
- $\mathcal{F}(p \cdot q) = \mathcal{F}(p) \otimes \mathcal{F}(q)$
- $\mathcal{F}(p^\dagger) = \mathcal{F}(p^\dagger) = \mathcal{F}(p)$
- $\mathcal{F}(p \leq q) = \mathcal{F}(p) \to \mathcal{F}(q)$
- $\mathcal{F}(\epsilon^\dagger) = \mathcal{F}(\epsilon^\dagger) = \text{inner product in FdVect}$
- $\mathcal{F}(\eta^\dagger) = \mathcal{F}(\eta^\dagger) = \text{identity maps in FdVect}$

[Kartsaklis, Sadrzadeh, Pulman and Coecke, 2016]
A multi-linear model

The grammatical type of a word defines the vector space in which the word lives:

- Nouns are vectors in $N$;
- Adjectives are linear maps $N \rightarrow N$, i.e. elements in $N \otimes N$;
- Intransitive verbs are linear maps $N \rightarrow S$, i.e. elements in $N \otimes S$;
- Transitive verbs are bi-linear maps $N \otimes N \rightarrow S$, i.e. elements of $N \otimes S \otimes N$;

The composition operation is tensor contraction, i.e. elimination of matching dimensions by application of inner product.
Categorical composition: example

**Type reduction morphism:**

\[
(\epsilon^r_n \cdot 1_s) \circ (1_n \cdot \epsilon^l_n \cdot 1_{n^r \cdot s} \cdot \epsilon^l_n) : n \cdot n^l \cdot n \cdot n^r \cdot s \cdot n^l \cdot n \rightarrow s
\]

\[
\mathcal{F} \left[ (\epsilon^r_n \cdot 1_s) \circ (1_n \cdot \epsilon^l_n \cdot 1_{n^r \cdot s} \cdot \epsilon^l_n) \right] (\text{trembling} \otimes \text{shadows} \otimes \text{play} \otimes \text{hide-and-seek}) =
\]

\[
(\epsilon_N \otimes 1_S) \circ (1_N \otimes \epsilon_N \otimes 1_{N \otimes S} \otimes \epsilon_N) (\text{trembling} \otimes \text{shadows} \otimes \text{play} \otimes \text{hide-and-seek}) =
\]

\[
\text{trembling} \otimes \text{shadows} \otimes \text{play} \otimes \text{hide-and-seek}
\]

\[
\text{shadows, hide-and-seek} \in N \quad \text{trembling} \in N \otimes N \quad \text{play} \in N \otimes S \otimes N
\]
Vectors and tensors are states: \( \overrightarrow{v} : I \to V, \overrightarrow{w} : I \to V \otimes V \) and so on.
Graphical language: example

\[ \mathcal{F}(N \ V \ N, \ \text{Adj trembling shadows \ play \ hide-and-seek}) = N \ N' \ N \ N' S \ N' \ N \]

\[ \mathcal{F}(\alpha)(\text{trembling} \otimes \text{shadows} \otimes \text{play} \otimes \text{hide-and-seek}) \]

4. Dealing with Functional Words
5. A Quantum Perspective
6. Conclusions and Future Work
Extensional approach

Grefenstette and Sadrzadeh (2011); Kartsaklis and Sadrzadeh (2016):

A relational word is defined as the set of its arguments:

\[
\text{[red]} = \{\text{car, door, dress, ink, \cdots}\}
\]

To give this linear-algebraically:

\[
\overrightarrow{adj} = \sum_{i} \overrightarrow{\text{noun}_i} \otimes \overrightarrow{\text{noun}_i}
\]

When composing the adjective with a new noun \( n' \), we get:

\[
\overrightarrow{adj} \times \overrightarrow{n'} = \sum_{i} \langle \overrightarrow{\text{noun}_i}, \overrightarrow{n'} \rangle \overrightarrow{\text{noun}_i}
\]
Statistical approach

Baroni and Zamparelli (2010):

Create holistic distributional vectors for whole compounds (as if they were words) and use them to train a linear regression model.

\[
\hat{adj} = \arg \min_{adj} \left[ \frac{1}{2m} \sum_i (\hat{adj} \times \text{noun}_i - \hat{adj} \cdot \text{noun}_i)^2 \right]
\]
Decomposition of tensors

- 3rd-order tensors for transitive verbs (and 4th-order for ditransitive verbs) pose a challenge
- We can reduce the number of parameters by applying canonical polyadic decomposition:

\[
\text{verb} = \sum_{r=1}^{R} P_r \otimes Q_r \otimes R_r
\]

\[
P \in \mathbb{R}^{R \times S}, \quad Q \in \mathbb{R}^{R \times N}, \quad R \in \mathbb{R}^{R \times N}
\]

- Keep \( R \) sufficiently small with regard to \( S \) and \( N \)
- Learn \( P, Q \) and \( R \) by multi-linear regression

\[
\overrightarrow{sv\theta} = f(\overrightarrow{s}, \overrightarrow{\theta}) := P^T(Q \overrightarrow{s} \odot R \overrightarrow{\theta})
\]

\[
L = \frac{1}{2m} \sum_{i=1}^{m} \|f(\overrightarrow{s}_i, \overrightarrow{\theta}_i) - \overrightarrow{t}_i\|^2
\]

[Fried, Polajnar, Clark (2015)]
Outline

1. Distributional Semantics
2. Categorical Compositional Distributional Semantics
3. Creating Relational Tensors
4. Dealing with Functional Words
5. A Quantum Perspective
6. Conclusions and Future Work
Certain classes of words, such as determiners, relative pronouns, prepositions, or coordinators occur in almost every possible context.

Thus, they are considered \textit{semantically vacuous} from a distributional perspective and most often they are simply ignored.

In the tensor-based setting, these special words can be modelled by exploiting additional mathematical structures, such as Frobenius algebras and bialgebras.
Frobenius algebras in \( \text{FdVect} \)

- Given a symmetric CCC \((\mathcal{C}, \otimes, I)\), an object \(X \in \mathcal{C}\) has a Frobenius structure on it if there exist morphisms:
  \[
  \Delta : X \to X \otimes X, \quad \iota : X \to I \quad \text{and} \quad \mu : X \otimes X \to X, \quad \zeta : I \to X
  \]
  conforming to the Frobenius condition:
  \[
  (\mu \otimes 1_X) \circ (1_X \otimes \Delta) = \Delta \circ \mu = (1_X \otimes \mu) \circ (\Delta \otimes 1_X)
  \]

- In \( \text{FdVect} \), any vector space \( V \) with a fixed basis \( \{ v_i \} \) has a commutative special Frobenius algebra over it [Coecke and Pavlovic, 2006]:
  \[
  \Delta : v_i \mapsto v_i \otimes v_i \quad \mu : v_i \otimes v_i \mapsto v_i
  \]
  It can be seen as copying and merging of the basis.
Graphical representation

- Frobenius maps:

$$\left(\Delta, \iota\right) = \begin{array}{c}
\includegraphics[width=0.3\textwidth]{frobenius_map1}
\end{array} \quad \left(\mu, \zeta\right) = \begin{array}{c}
\includegraphics[width=0.3\textwidth]{frobenius_map2}
\end{array}$$

- Frobenius condition:
In *FdVect*, the merging $\mu$-map becomes element-wise vector multiplication:

$$\mu(\vec{v}_1 \otimes \vec{v}_2) = \vec{v}_1 \odot \vec{v}_2 = \begin{array}{c}
\vec{v}_1 \\
\downarrow \\
V \\
\uparrow \\
\vec{v}_2
\end{array}$$

- An alternative form of composition between operands of the same order; both of them *contribute equally* to the final result.
- Different from standard $\epsilon$-composition, which has a *transformational* effect. An intransitive verb, for example, is a map $N \rightarrow S$ that transforms a noun into a sentence:

$$\begin{array}{c}
\uparrow \\
N \\
\downarrow \\
\bigcirc \\
N' \\
\downarrow \\
\downarrow \\
\downarrow \\
I \\
\uparrow \\
S
\end{array}$$
Merging (2/2)

Applications of merging in linguistics:

- Noun modification by relative clauses [Sadrzadeh et al., MoL 2013]
- Modelling intonation at sentence level [Kartsaklis and Sadrzadeh, MoL 2015]
- Modelling non-compositional compounds (e.g. ‘pet-fish’) [Coecke and Lewis, QI 2015]
- Modelling coordination [Kartsaklis (2016)]
Copy

- In **FdVect**, the $\Delta$-map converts vectors to diagonal matrices.
- It can be seen as *duplication* of information; a single wire is split in two; i.e. a maximally entangled state.
- A form of *type-raising* (converts an atomic type to a function) 
  [Kartsaklis et al., COLING 2012]:

  ![Diagram]

  A means of *syntactic movement*; the same word can efficiently interact with different parts of the sentence [Sadrzadeh et al., MoL 2013]
Coordination

The grammatical connection of two or more words, phrases, or clauses to give them equal emphasis and importance. The connected elements, or conjuncts, behave as one.

Merging and copying are the key processes of coordination:

\[ \text{context } c_1 \text{ conj } c_2 \leftrightarrow [\text{context } c_1] \text{ conj } [\text{context } c_2] \]

(1) Mary studies [philosophy] and [history] \(\models\) [Mary studies philosophy] and [Mary studies history]

(2) John [sleeps] and [snores] \(\models\) [John sleeps] and [John snores]
Coordinating atomic types

Coordination morphism:

\[
\text{coord}_{X} : I \overset{\eta_{X} \otimes \eta_{X}}{\longrightarrow} X^{r} \otimes X \otimes X \otimes X^{l} \overset{1_{X^{r}} \otimes \mu_{X} \otimes 1_{X^{l}}}{\longrightarrow} X^{r} \otimes X \otimes X^{l}
\]

\[
\begin{array}{c}
\text{apples} \quad \text{and} \quad \text{oranges} \\
\downarrow \quad \downarrow \quad \downarrow \\
N \quad N^{r} \quad N \quad N^{l} \quad N \quad N^{r} \quad N \quad N^{l} \\
\end{array}
\]

\[
\begin{array}{c}
\text{apples} \quad \text{and} \quad \text{oranges} \\
\downarrow \quad \downarrow \quad \downarrow \\
N \quad N^{r} \quad N \quad N^{l} \quad N \quad N^{r} \quad N \quad N^{l} \\
\end{array}
\]

\[
\begin{array}{c}
\text{apples} \quad \text{and} \quad \text{oranges} \\
\downarrow \quad \downarrow \quad \downarrow \\
N \quad N^{r} \quad N \quad N^{l} \quad N \quad N^{r} \quad N \quad N^{l} \\
\end{array}
\]

\[
(\epsilon_{N}^{r} \otimes 1_{N} \otimes \epsilon_{N}^{l}) \circ (\text{apples} \otimes \text{coord}_{N} \otimes \text{oranges}) = \mu(\text{apples} \otimes \text{oranges}) = \text{apples} \odot \text{oranges}
\]

\[
\begin{array}{c}
\text{men} \quad \text{watch} \quad \text{football} \\
\downarrow \quad \downarrow \quad \downarrow \quad \downarrow \quad \downarrow \\
N \quad N^{r} \quad S \quad N^{l} \quad N \quad S^{r} \quad S \quad S^{l} \quad N \quad N^{r} \quad S \quad S^{l} \quad N \quad N^{r} \quad S \quad S^{l} \\
\end{array}
\]

\[
\begin{array}{c}
\text{men} \quad \text{watch} \quad \text{football} \quad \text{women} \quad \text{knit} \\
\downarrow \quad \downarrow \quad \downarrow \quad \downarrow \quad \downarrow \\
N \quad N^{r} \quad S \quad N^{l} \quad N \quad S^{r} \quad S \quad S^{l} \quad N \quad N^{r} \quad S \quad S^{l} \quad N \quad N^{r} \quad S \quad S^{l} \\
\end{array}
\]

\[
(\text{men}^{T} \times \text{watch} \times \text{football}) \odot (\text{women}^{T} \times \text{knit})
\]
Coordinating compound types

- Lifting the maps to compound objects gives:

- For the case of a verb phrase, we get:
Coordinating verb phrases

The subject of the coordinate structure ('John') is copied at the $N^r$ input of the coordinator;

the first branch interacts with verb ‘sleeps’ and the second one with verb ‘snores’; and

the $S$ wires of the two verbs that carry the individual results are merged together with $\mu$-composition.

$$\overrightarrow{John}^T \times (\overrightarrow{sleep} \odot \overrightarrow{snore})$$

($\odot$ here denotes the Hadamard product between matrices)
1. Distributional Semantics
2. Categorical Compositional Distributional Semantics
3. Creating Relational Tensors
4. Dealing with Functional Words
5. A Quantum Perspective
6. Conclusions and Future Work
We take words to be “quantum systems”, and word vectors specific states of these systems:

\[ |w⟩ = c_1|k_1⟩ + c_2|k_2⟩ + \ldots + c_n|k_n⟩ \]

Each element of the ONB \{|k_i⟩\}_i is essentially an atomic symbol:

\[ |cat⟩ = 12|milk⟩ + 8|cute⟩ + \ldots + 0|bank⟩ \]

In other words, a word vector is a probability distribution over atomic symbols

\[ |w⟩ \] is a pure state: when word \( w \) is seen alone, it is like co-occurring with all the basis words with strengths denoted by the various coefficients.
Lexical ambiguity

We distinguish between two types of lexical ambiguity:

- In cases of **homonymy** (organ, bank, vessel etc.), due to some historical accident the same word is used to describe two (or more) completely unrelated concepts.

- **Polysemy** relates to subtle deviations between the different senses of the same word.
Ideally, every disjoint meaning of a homonymous word must be represented by a distinct pure state:

\[ |\text{bank}_{\text{fin}}\rangle = a_1 |k_1\rangle + a_2 |k_2\rangle + \ldots + a_n |k_n\rangle \]

\[ |\text{bank}_{\text{riv}}\rangle = b_1 |k_1\rangle + b_2 |k_2\rangle + \ldots + b_n |k_n\rangle \]

- \( \{a_i\}_i \neq \{b_i\}_i \), since the financial sense and the river sense are expected to be seen in drastically different contexts
- So we have two distinct states describing the same system
- We cannot be certain under which state our system may be found – we only know that the former state is more probable than the latter
- In other words, the system is better described by a probabilistic mixture of pure states, i.e. a \textit{mixed state}. 
Density operators

- Mathematically, a mixed state is represented by a density operator:
  \[ \rho(w) = \sum_i p_i |s_i\rangle\langle s_i| \]

- For example:
  \[ \rho(bank) = 0.80 |bank_{fin}\rangle\langle bank_{fin}| + 0.20 |bank_{riv}\rangle\langle bank_{riv}| \]

- A density operator is a probability distribution over vectors.

Properties of a density operator \( \rho \)

- Positive semi-definite: \( \langle v | \rho | v \rangle \geq 0 \quad \forall v \in \mathcal{H} \)
- Of trace one: \( \text{Tr}(\rho) = 1 \)
- Self-adjoint: \( \rho = \rho^\dagger \)
Complete positivity: The CPM construction

In order to apply the new formulation on the categorical model of Coecke et al. we need:

- to replace word vectors with density operators
- to replace linear maps with completely positive linear maps, i.e. maps that send positive operators to positive operators while respecting the monoidal structure.

Selinger (2007):

Any dagger compact closed category is associated with a category in which the objects are the objects of the original category, but the maps are completely positive maps.
From vectors to density operators

- The passage from a grammar to distributional meaning is defined according to the following composition:

$$P(\Sigma, B) \xrightarrow{\mathcal{F}} \text{FdHilb} \xrightarrow{\mathcal{L}} \text{CPM}(\text{FdHilb})$$

- The meaning of a sentence $w_1 w_2 \ldots w_n$ with grammatical derivation $\alpha$ becomes:

$$\mathcal{L}(\mathcal{F}(\alpha)) (\rho(w_1) \otimes_{\text{CPM}} \rho(w_2) \otimes_{\text{CPM}} \ldots \otimes_{\text{CPM}} \rho(w_n))$$

- Composition takes this form:

Subject-intransitive verb: $\rho_{IN} = \text{Tr}_N(\rho(v) \circ (\rho(s) \otimes 1_S))$

Adjective-noun: $\rho_{AN} = \text{Tr}_N(\rho(adj) \circ (1_N \otimes \rho(n)))$

Subj-trans. verb-Obj: $\rho_{TS} = \text{Tr}_{N,N}(\rho(v) \circ (\rho(s) \otimes 1_S \otimes \rho(o)))$

[Kartsaklis DPhil thesis (2015)]

[Piedeleu, Kartsaklis, Coecke, Sadrzadeh (2015)]
Entropy as degree of ambiguity

Von Neumann entropy:

For a d.m. $\rho$ with eigen-decomposition $\sum_i e_i |n_i\rangle \langle n_i|$:  

$$S(\rho) = -\text{Tr}(\rho \ln \rho) = -\sum_i e_i \ln e_i$$

- Von Neumann entropy shows how ambiguity evolves from words to compounds
- **Disambiguation = purification**: Entropy of ‘vessel’ is 0.25, but entropy of ‘vessel that sails’ is 0.01 (i.e. almost a pure state).
Conclusions and future work

Main points:

- Tensor-based models of meaning provide a linguistically motivated procedure for computing the meaning of phrases and sentences.
- Words of relational nature, such as verbs and adjectives, become (multi-)linear maps acting on noun vectors.
- A test-bed for studying compositional aspects of language at a deeper level.

Future work:

- The application of a logic remains an open problem.
- The density-operator formulation opens various new possibilities to be explored in the future.
- A large-scale evaluation on unconstrained text is remain to be done.
Thank you for listening... and any questions?
