Abstract

We introduce the notion of simultaneous core multipartitions, generalising simultaneous core partitions, which have been studied extensively in the recent literature. Given a multipartition datum \(ps|c\), which consists of a non-negative integer \(s\) and an \(l\)-tuple \(c\) of integers, we introduce the notion of an \(ps|c\)-core multipartition. Given an arbitrary set of multipartition data, we give necessary and sufficient conditions for the corresponding set of simultaneous core multipartitions to be finite. We then study the special case of simultaneous core bipartitions, giving exact enumerative results in some special subcases.

1 Introduction

The study of integer partitions has a long history, with applications in a variety of areas. In the last few years there has been considerable interest in core partitions, i.e. partitions with no hook lengths divisible by a certain prescribed integer. Of particular interest are simultaneous core partitions, i.e. partitions which are both \(s\)- and \(t\)-cores, for given (typically coprime) integers \(s, t\). Various enumerative results have been proved for these \("(s, t)\)-cores"; foremost among these are Anderson’s theorem [An] giving the number of \((s, t)\)-cores, and Armstrong’s Conjecture (stated in [AHJ], and proved by Johnson in [J]) giving the average size of an \((s, t)\)-core.

In this paper we introduce the subject of core multipartitions. For a fixed \(l \in \mathbb{N}\), an \(l\)-multipartition is just an \(l\)-tuple of partitions. We generalise the notion of core partition to multipartitions by using a characterisation of core partitions in terms of residues of nodes which goes back to a result of Littlewood [Li]. Our definition of core multipartitions has representation-theoretic significance in terms of modules for cyclotomic Hecke algebras. The extension to multipartitions requires not just an integer \(s\) but also an \(l\)-tuple \(c \in \mathbb{Z}^l\); so we actually introduce the notion of an \((s \mid c)\)-core multipartition (or simply an \((s \mid c)\)-core). We can then consider the question of simultaneous core multipartitions, i.e. multipartitions which are \((s \mid c)\)-cores for all pairs \((s \mid c)\) in a given set \(\mathcal{T}\). Our main result is a determination of exactly when there are only finitely such multipartitions.

Having established this finiteness result, we consider enumerative results, restricting to the first non-trivial case where \(l = 2\) and \(|\mathcal{T}| = 2\) and enumerating simultaneous core bipartitions in two special subcases.
2 Definitions and basic results

In this section we set out some definitions and notation.

2.1 Standard notation

If \(X\) is any subset of \(\mathbb{Z}^l\) and \(s \in \mathbb{N}\), then we write \(n + sX = \{n + sx \mid x \in X\}\). We define \(\mathbb{Z}/s\mathbb{Z}\) to be the set \(\{n + s\mathbb{Z} \mid n \in \mathbb{Z}\}\). (We do not employ the popular abuse of notation in which \(\mathbb{Z}/s\mathbb{Z} = \{0, \ldots, s-1\}\).) A \(\mathbb{Z}/s\mathbb{Z}\)-tuple of integers just means a function \(u\) from \(\mathbb{Z}/s\mathbb{Z}\) to \(\mathbb{Z}\), which we write in the form \((u_i \mid i \in \mathbb{Z}/s\mathbb{Z})\).

2.2 Partitions

A partition is a weakly decreasing sequence \(\lambda = (\lambda_1, \lambda_2, \ldots)\) of non-negative integers with finite sum. When writing partitions, we typically group together equal parts with a superscript and omit the trailing zeroes, and we write the partition \((0,0,\ldots)\) as \(\emptyset\). We let \(\mathcal{P}\) denote the set of all partitions.

The size of a partition \(\lambda\) is the sum \(|\lambda| = \sum_{a \geq 1} \lambda_a\). The Young diagram of \(\lambda\) is the set

\[
[\lambda] = \{(a,b) \in \mathbb{N}^2 \mid b \leq \lambda_a\}
\]

whose elements we call the nodes of \(\lambda\). We draw \([\lambda]\) as an array of boxes in plane using the English convention, in which the Young diagram of \((6,4,2,1^2)\) is drawn as follows.

![Young diagram example](image)

A node of \(\lambda\) is removable if it can be removed to leave a Young diagram (i.e. if it has the form \((a, \lambda_a)\), with \(\lambda_a > \lambda_{a+1}\)), while a pair \((a,b) \notin [\lambda]\) is an addable node of \([\lambda]\) if it can be added to \([\lambda]\) to yield a Young diagram. The rim of \(\lambda\) is the set of all \((a,b) \in [\lambda]\) for which \((a+1, b+1) \notin [\lambda]\).

A rim hook of \(\lambda\) is a set of consecutive nodes of the rim which can be removed to leave the Young diagram of a smaller partition. If \(s \in \mathbb{N}\), then a rim \(s\)-hook is a rim hook containing exactly \(s\) nodes. \(\lambda\) is an \(s\)-core partition (or simply an \(s\)-core) if it has no rim \(s\)-hooks.

For example, the highlighted nodes in the diagram below comprise a rim 5-hook of \((6,4,2,1^2)\), so this partition is not a 5-core. On the other hand, one can easily check that this partition has no rim 3-hooks, so is a 3-core.

![Rim hook example](image)

We write \(\mathcal{C}_s\) for the set of all \(s\)-core partitions. These partitions can also be characterised in terms of residues of nodes. Given a node \((a,b) \in [\lambda]\), define its \(s\)-residue to be \(b - a + s\mathbb{Z}\). For
example, the 3-residues of the nodes of \( (6, 4, 2, 1^2) \) are illustrated in the following diagram (in which we label a node of residue \( i + 3\mathbb{Z} \) with \( i \), for \( i = 0, 1, 2 \)).

\[
\begin{array}{cccc}
0 & 1 & 2 & 0 \\
2 & 0 & 1 & 2 \\
1 & 2 \\
0 \\
2
\end{array}
\]

The \( s \)-content of a partition \( \lambda \) is defined to be the multiset of \( s \)-residues of the nodes of \( \lambda \). From the diagram above, we see that the 3-content of \( (6, 4, 2, 1^2) \) is \( \{(0 + 3\mathbb{Z})^4, (1 + 3\mathbb{Z})^4, (2 + 3\mathbb{Z})^6\} \) (where we adopt what we hope is an obvious notation for a multiset of elements of \( \mathbb{Z}/s\mathbb{Z} \)).

The \( s \)-content of a partition is significant because of the following result.

**Theorem 2.1 [Li].** Suppose \( \lambda \in \mathcal{P} \) and \( s > 1 \). Then \( \lambda \) is an \( s \)-core if and only if there is no other partition with the same \( s \)-content as \( \lambda \).

Now suppose \( s_1, \ldots, s_r \in \mathbb{N} \). An \( (s_1, \ldots, s_r) \)-core means a partition which is an \( s_i \)-core for each \( i \). It is fairly easy to show that the set of \( (s_1, \ldots, s_r) \)-cores is finite if and only if \( s_1, \ldots, s_r \) are coprime; this appears to have been written down for the first time by Vandehey [V]. Our main aim in this paper is to generalise this statement to multipartitions, which we introduce next.

### 2.3 Multipartitions

Fix \( l \in \mathbb{N} \). An \( l \)-multipartition is an \( l \)-tuple \( \lambda = (\lambda^{(1)}, \ldots, \lambda^{(l)}) \) of partitions, which we call the components of \( \lambda \). We write \( \mathcal{P}^l \) for the set of all \( l \)-multipartitions, and we write \( \emptyset^l \) for the multipartition \( (\emptyset, \ldots, \emptyset) \).

The size of an \( l \)-multipartition \( \lambda \) is the sum of the sizes of its components. The Young diagram of \( \lambda \) is the set

\[
[\lambda] = \{(a, b, k) \in \mathbb{N}^2 \times \{1, \ldots, l\} \mid b \leq \lambda^{(k)}_a\},
\]

whose elements we call the nodes of \( \lambda \). We draw the Young diagram of \( \lambda \) by drawing the Young diagrams of \( \lambda^{(1)}, \ldots, \lambda^{(l)} \) in order from left to right. We define addable and removable nodes of multipartitions analogously to those for partitions.

Now take an \( l \)-tuple \( c = (c_1, \ldots, c_l) \in \mathbb{Z}^l \), and define the \( (s \mid c) \)-residue of a node \((a, b, k)\) to be \( b - a + c_k + s\mathbb{Z} \). We refer to a node of \( (s \mid c) \)-residue \( i \in \mathbb{Z}/s\mathbb{Z} \) as an \( i \)-node. Define the \( (s \mid c) \)-content of \( \lambda \) to be the multiset of \( (s \mid c) \)-residues of the nodes of \( \lambda \). For example, suppose \( l = 3 \), \( s = 4 \) and \( c = (0, 2, 1) \). For \( \lambda = ((2), (4, 1^2), (1^2)) \), the residues are indicated by the following diagram.

\[
\begin{array}{cccc}
0 & 1 & 2 & 3 \\
1 & 0 \\
0
\end{array}
\]

We see that the \( (4 \mid (0, 2, 1)) \)-content of \( \lambda \) is \( \{(0 + 4\mathbb{Z})^4, (1 + 4\mathbb{Z})^4, (2 + 4\mathbb{Z})^1, (3 + 4\mathbb{Z})^1\} \).

Now, inspired by Theorem 2.1, we make the following definition: say that \( \lambda \in \mathcal{P}^l \) is an \( (s \mid c) \)-core multipartition (or simply an \( (s \mid c) \)-core) if there is no other \( l \)-multipartition \( \mu \) with the same \( (s \mid c) \)-content. We write \( \mathcal{C}_{(s \mid c)} \) for the set of all \( (s \mid c) \)-cores.
In the rest of the paper we will refer to the pair \((s \mid c)\) as an \(l\)-multipartition datum. If we wish to refer to the individual integers \(c_1, \ldots, c_l\), we may write \((s \mid c_1, \ldots, c_l)\) instead of \((s \mid c)\) in any of the notation introduced above. For example, we can easily check that the multipartition \(\lambda\) above lies in \(C_{(4 \mid 0,2,1)}\).

Remarks.

1. The definition of the \((s \mid c)\)-residue of a node (and hence of an \((s \mid c)\)-core) depends only on the residues of \(c_1, \ldots, c_l\) modulo \(s\); so we could just as easily take \(c \in (\mathbb{Z}/s\mathbb{Z})^l\) rather than \(c \in \mathbb{Z}^l\) in the definition. It will be slightly more convenient to take \(c_1, \ldots, c_l\) to be integers. Note also that the set \(\mathcal{C}_{(s \mid c)}\) is unchanged if \(c_1, \ldots, c_l\) are all translated by a fixed integer (since the effect is just to shift the residues of all nodes by this same integer).

2. In the study of \(s\)-core partitions \(s\) is typically assumed to be greater than 1. However, one can meaningfully consider the cases \(s = 0\) and \(s = 1\). First take \(s = 1\); according to the definition using rim hooks, the only 1-core partition is \(\varnothing\). However, the partition \(1\) is the unique partition with its 1-content (which is why we need to assume \(s \neq 1\) in Theorem 2.1). Nevertheless, most of the theory of core partitions applies (in a trivial way) with \(s = 1\), if we take \(\mathcal{C}_1 = \{\varnothing\}\). Similarly for multipartitions, we take \(\mathcal{C}_{(1 \mid c)} = \{\varnothing\}\) (which is consistent with the definition of core multipartitions given above provided \(l \geq 2\)), and the results we prove below will apply in this case.

Now consider the case \(s = 0\). In this case we should regard the residue of a node \((a,b)\) as the integer \(b - a\), and correspondingly define the 0-content to be a multiset of integers. It is then not hard to prove that any partition is determined by its 0-content, so every partition is a 0-core.

The situation with multipartitions is less straightforward when \(s = 0\). Given \(c \in \mathbb{Z}^l\) we define the \((0 \mid c)\)-residue of the node \((a,b,k)\) to be the integer \(b - a + c_k\), so that the \((0 \mid c)\)-content is again a multiset of integers. But now not every multipartition is a \((0 \mid c)\)-core. In fact this is easily seen: if \(c_j = c_k\) for some \(j \neq k\), then a multipartition \(\lambda\) has the same \((0 \mid c)\)-content as the multipartition obtained by switching the components \(\lambda^{(j)}\) and \(\lambda^{(k)}\), so cannot be a \((0 \mid c)\)-core if these components are unequal. So the study of \((0 \mid c)\)-core multipartitions is certainly non-trivial, and we will include the case \(s = 0\) in our considerations in this paper.

The case \(s = 0\) can be regarded as the limiting case as \(s\) gets very large (in fact, this situation is often described as \(s = \infty\) rather than \(s = 0\)): given a multipartition \(\lambda\) and \(c \in \mathbb{Z}^l\), it is easily seen that we have \(\lambda \in C_{(0 \mid c)}\) if and only if \(\lambda \in C_{(s \mid c)}\) for all sufficiently large \(s\).

3. Our definition of core multipartition is not completely arbitrary, but has representation-theoretic significance. Associated to a pair \((s \mid c)\) as above and a positive integer \(n\) is an Ariki–Koike algebra (a Hecke algebra of the complex reflection group of type \(G(l,1,n)\)). This algebra has an important family of modules (the Specht modules) labelled by \(l\)-multipartitions of size \(n\). Lyle & Mathas [LM] showed that two multipartitions having the same \((s \mid c)\)-content is equivalent to the corresponding Specht modules lying in the same block of the Ariki–Koike algebra, and the author [F1] showed that a multipartition being an \((s \mid c)\)-core is equivalent to the corresponding Specht module being contained in a simple block. This is analogous to the significance of \(s\)-cores in the \(s\)-modular representation theory of the symmetric group (or more generally the Iwahori–Hecke algebra of type \(A\)).
In fact, this analogy goes further: in [F1] the author defines a “weight” function on multipartitions (depending on $s, c$) which is an analogue of the $s$-weight of a partition $\lambda$ (i.e. the number of rim $s$-hooks that need to be removed to reach the $s$-core of $\lambda$). $(s \mid c)$-cores are then simply multipartitions of weight 0.

### 2.4 Basic results

In this section we will give some basic results on core multipartitions; in particular, we will give a simple condition in terms of beta-numbers for a multipartition to be an $(s \mid c)$-core. Some of the background is taken from [F1], in which (as described above) the author introduces a function called weight (depending on a multipartition datum $(s \mid c)$) on $l$-multipartitions. Theorem 4.1 in [F1] says that a multipartition is an $(s \mid c)$-core if and only if it has weight 0. The results in [F1, Section 3] yield a simple algorithm for computing the weight of a partition; below, we give simplified versions of some of these results which are sufficient to determine whether a multipartition has weight 0.

We begin with a very simple observation.

**Lemma 2.2.** Suppose $(s \mid c)$ is an $l$-multipartition datum, and $\lambda \in \mathcal{C}_{(s \mid c)}$. Then each component of $\lambda$ is an $s$-core.

**Proof.** We prove the contrapositive. Suppose $\lambda^{(k)}$ is not an $s$-core. Then by Theorem 2.1 there is another partition $\mu$ with the same $s$-content as $\lambda^{(k)}$. The multipartition obtained from $\lambda$ by replacing $\lambda^{(k)}$ with $\mu$ then has the same $s \mid c$-content as $\lambda$, so $\lambda$ is not an $(s \mid c)$-core.

The next result shows that to check whether a multipartition is an $(s \mid c)$-core we can reduce to the case $l = 2$.

**Proposition 2.3 [F1, Proposition 3.5].** Suppose $(s \mid c)$ is an $l$-multipartition datum, and that $\lambda^{(k)} \in \mathcal{C}_s$ for every $k$. Then $\lambda$ is an $(s \mid c)$-core if and only if $(\lambda^{(j)}, \lambda^{(k)})$ is an $(s \mid c_j, c_k)$-core bipartition for all $1 \leq j < k \leq l$.

To go further, we recall the definition of beta-numbers, which goes back to Nakayama [N]. Define the beta-set of a partition $\lambda$ to be the set

$$\mathcal{B}^\lambda = \{ \lambda_a - a \mid a \in \mathbb{N} \}.$$ 

For any $c \in \mathbb{Z}$, we write $\mathcal{B}^\lambda_c$ for the set $\mathcal{B}^\lambda + c$, which we refer to as the $c$-shifted beta-set of $\lambda$.

The following result is due to Robinson [R, (2.8)].

**Proposition 2.4.** Suppose $s \geq 0$ and $\lambda \in \mathcal{P}$. Then the number of rim $a$-hooks of $\lambda$ equals the number of $b \in \mathcal{B}^\lambda$ such that $b - s \notin \mathcal{B}^\lambda$. In particular, $\lambda$ is an $s$-core if and only if $\mathcal{B}^\lambda \subseteq \mathcal{B}^{\lambda}_{s}$.

This result is key in the study of core partitions; it yields James’s abacus model for partitions, which in turn leads to a geometric interpretation for the set of $s$-cores.

It turns out that core multipartitions can also be characterised in terms of the beta-sets of their components. In view of Proposition 2.3 we restrict to the case $l = 2$. The next two results are special cases of the results in [F1, §3.4].

**Proposition 2.5.** Suppose $c, d \in \mathbb{Z}$ and $(\lambda, \mu) \in \mathcal{P}^2$.

- If $c \leq d$, then $(\lambda, \mu) \in \mathcal{C}_{(0 \mid c, d)}$ if and only if $\mathcal{B}_c^\lambda \subseteq \mathcal{B}_d^\mu$.
• If \( c \geq d \), then \((\lambda, \mu) \in C(0, c, d)\) if and only if \( B^\lambda_c \supseteq B^\mu_d \).

**Proposition 2.6.** Suppose \( s \in \mathbb{N} \) and \( c, d \in \mathbb{Z} \), and let \( e \) be the residue of \( c - d \) modulo \( s \). Suppose \((\lambda, \mu) \in P^2\). Then \((\lambda, \mu) \in C(s, c, d)\) if and only if

\[
B^\lambda_e \supseteq B^\mu_d \supseteq B^\lambda_{e-s}.
\]

We make an observation about beta-sets which will be useful later. Suppose \( \lambda, \mu \in P \) and \( c, d \in \mathbb{Z} \). Note that \( B^\lambda_c \) is a set of integers which is bounded above and whose complement in \( \mathbb{Z} \) is bounded below. Moreover, the number of non-negative integers in \( B^\lambda_c \) minus the number of negative integers not in \( B^\lambda_c \) equals \( c \). As a consequence, if \( B^\lambda_c \supseteq B^\mu_d \) then \( c \geq d \) and \( |B^\lambda_c \setminus B^\mu_d| = c - d \).

### 2.5 Action of the affine symmetric group

One of the most interesting and useful features of the set of \( s \)-cores is that it admits a natural action of the affine symmetric group. In this section, we show how this generalises to core multipartitions. This provides a natural proof of the fact that (provided \( s \neq 1 \)) the set \( C(s, c) \) is infinite.

Take \( s \geq 2 \). Recall that the **affine symmetric group** \( \tilde{S}_s \) is the group of all permutations \( g \) of \( \mathbb{Z} \) with the properties that

- \( g(n + s) = g(n) + s \) for all \( n \in \mathbb{Z} \), and
- \( g(0) + g(1) + \cdots + g(s - 1) = 0 + 1 + \cdots + s - 1 \).

Then \( \tilde{S}_s \) is a Coxeter group, with generating set \( \{ s_i \mid i \in \mathbb{Z}/s\mathbb{Z} \} \) defined by

\[
s_i(n) = \begin{cases} 
  n + 1 & (n \in i - 1) \\
  n - 1 & (n \in i) \\
  n & (n \notin i - 1, i) 
\end{cases}
\]

for \( i \in \mathbb{Z}/s\mathbb{Z} \) and \( n \in \mathbb{Z} \). The subgroup \( \tilde{S}_s^0 \) generated by \( \{ s_i \mid i \neq s\mathbb{Z} \} \) is naturally isomorphic to the symmetric group \( S_s \).

Now suppose \( \lambda \) is a partition and \( i \in \mathbb{Z}/s\mathbb{Z} \). Define \( s_i(\lambda) \) to be the partition obtained by simultaneously adding all the addable \( i \)-nodes to \( \lambda \) and removing all the removable \( i \)-nodes. This defines an action of \( \tilde{S}_s \) on the set of all partitions. Moreover, the set \( C_s \) is an orbit for this action, so we have a transitive action of \( \tilde{S}_s \) on \( C_s \). This action was first studied by Lascoux [La], who showed that the stabiliser of the empty partition is the subgroup \( \tilde{S}_s^0 \) defined above, so that \( s \)-cores are naturally in bijection with left cosets of \( \tilde{S}_s^0 \) in \( \tilde{S}_s \).

Next suppose we shift all residues of nodes in \( \mathbb{N}^2 \) by some fixed amount \( c \); that is, we redefine the residue of a node \((a, b)\) to be \( b - a + c + s\mathbb{Z} \). Then we can define another action of \( \tilde{S}_s \) on \( C_s \) in exactly the same way as defined above; this just amounts to twisting Lascoux’s action by the automorphism of \( \tilde{S}_s \) defined by \( s_i \mapsto s_{i+c} \) for all \( i \). We call this the **\( c \)-shifted action** of \( \tilde{S}_s \) on \( C_s \). The stabiliser of \( \emptyset \) under the \( c \)-shifted action is the parabolic subgroup \( \tilde{S}_s^c \) of \( \tilde{S}_s \) generated by \( \{ s_i \mid i \neq c + s\mathbb{Z} \} \).

Now we consider multipartitions. Suppose we have an \( l \)-multipartition datum \((s, c)\); for the moment we will continue to assume that \( s \geq 2 \) (we will comment below on the case \( s = 0 \)). We can define an action of \( \tilde{S}_s \) on \( P^l \) by adding all addable \( i \)-nodes and removing all removable \( i \)-nodes. Then we have the following.
Proposition 2.7. Under the action of $\tilde{S}_s$ on $P^l$ described above, $C_{(s|c)}$ is an orbit.

Proof. It follows from [F1, Lemma 3.6] that if $\lambda \in C_{(s|c)}$ and $i \in \mathbb{Z}/s\mathbb{Z}$ then $s_i(\lambda) \in C_{(s|c)}$. So $C_{(s|c)}$ is a union of orbits. To show that $C_{(s|c)}$ is a single orbit, we show that if $\lambda \in C_{(s|c)}$ with $\lambda \neq \emptyset^l$, then there is a strictly smaller multipartition in the same orbit; applying this repeatedly, we find that $\emptyset^l$ lies in the same orbit as $\lambda$.

The assumption that $\lambda \neq \emptyset^l$ mean that $\lambda$ has at least one removable node, of residue $i$, say. $\lambda$ cannot have any addable $i$-nodes, because then we could remove a removable $i$-node and add an addable $i$-node to obtain another multipartition with the same $(s|c)$-content, contradicting the assumption that $\lambda \in C_{(s|c)}$. So $s_i(\lambda)$ is obtained from $\lambda$ by removing $i$-nodes only, so is strictly smaller than $\lambda$, as required.

Of course, Proposition 2.7 can be used as an alternative definition of $C_{(s|c)}$ in the case $s \neq 1$: we can define $C_{(s|c)}$ to be the orbit containing $\emptyset^l$ under the action of $\tilde{S}_s$ on $P^l$.

Part of the action of $\tilde{S}_s$ on $C_{(s|c)}$ is illustrated in Figure 1 in the case $s = 3$ and $c = (0,1)$. In this diagram an arrow labelled $i$ indicates the action of $s_i + 3\mathbb{Z}$, for $i = 0, 1, 2$.

In order to understand this action in general, we find the stabiliser of $\emptyset^l$. This is easy to work out, given the discussion of the shifted actions of $\tilde{S}_s$ on $C_s$. It is clear from the definitions that $g \in \tilde{S}_s$ fixes $\emptyset^l$ if and only if it fixes $\emptyset$ under the $c_k$-shifted action of $\tilde{S}_s$ on $C_s$, for $k = 1, \ldots, l$. Hence the stabiliser of $\emptyset^l$ is the intersection $\tilde{S}_s^{-1} \cap \cdots \cap \tilde{S}_s^{-l}$. It is a standard fact in the theory of Coxeter groups that the intersection of a family of parabolic subgroups is the parabolic subgroup generated by the intersection of the generating sets of these subgroups. So the stabiliser of $\emptyset^l$ is the subgroup $\langle s_i \mid i \notin \{c_1 + s\mathbb{Z}, \ldots, c_l + s\mathbb{Z}\} \rangle$. Hence the set $C_{(s|c)}$ is in bijection with the set of left cosets of this subgroup.

We now consider the case $s = 0$. Here the discussion above applies, except that the finitely-generated Coxeter group $\tilde{S}_c$ is replaced with the finitary symmetric group, i.e. the group $\tilde{S}_{\infty}$ of all finitely-supported permutations of $\mathbb{Z}$. This is also a Coxeter group, with infinite generating set $\{s_i \mid i \in \mathbb{Z}\}$, where $s_j$ is the transposition $(i - 1, i)$. The stabiliser of $\emptyset^l$ under the action of $\tilde{S}_{\infty}$ on $C_{(0|c)}$ is $\langle s_i \mid i \notin \{c_1, \ldots, c_l\} \rangle$.

As a consequence of these actions, we deduce the following.

Proposition 2.8. Suppose $(s | c)$ is an $l$-multipartition datum. Then $C_{(s|c)}$ is infinite if and only if $s \neq 1$.

Proof. As noted above, when $s = 1$ the only $(s|c)$-core is $\emptyset^l$. The case where $s \neq 1$ follows from the discussion of actions above: the stabiliser of $\emptyset^l$ is easily seen to have infinite index in $\tilde{S}_s$ (in fact Hosaka [H, Theorem 3.1] shows that a proper parabolic subgroup of any infinite irreducible Coxeter group has infinite index), so $C_{(s|c)}$ is in bijection with an infinite set. □

3 Finiteness

In this section we prove our main result: given a set $\mathcal{T}$ of $l$-multipartition data, we determine whether there are only finitely many multipartitions which are $(s|c)$-cores for all $(s|c) \in \mathcal{T}$. We fix some notation.
Figure 1: The action of the affine symmetric group of degree 3 on $C_{(3|0,1)}$
Now the result follows from the definition of nodes of residue greater than residue. Hence two multipartitions with the same partition with this property are the same for every $l$. Now we can give our necessary condition for $C_T$ to be the greatest common divisor of the integers in the set $\{ s^{(l)} \mid t \in T \} \cup \{ c^{(l)}_i - c^{(l)}_j - c^{(u)}_i + c^{(u)}_j \mid t, u \in T, 1 \leq i, j \leq l \}$.

If the above set equals $\{0\}$ or is empty, then we set $g(T) = 0$.

3.1 A simple criterion

In this subsection we give a simple necessary condition for $C_T$ to be finite. It will turn out that in almost all cases this condition is also sufficient. We begin with a useful lemma.

**Lemma 3.1.** Suppose $s, t \in \mathbb{N} \cup \{0\}$ and $c \in \mathbb{Z}^l$, and that $s$ divides $t$. Then $C_{(s \mid c)} \subseteq C_{(t \mid c)}$.

**Proof.** Since $s$ divides $t$, two nodes with the same $(t \mid c)$-residue must have the same $(s \mid c)$-residue. Hence two multipartitions with the same $(t \mid c)$-content have the same $(s \mid c)$-content. Now the result follows from the definition of $(s \mid c)$-cores.

Note that when we say $s$ divides $t$, we mean that $t = ns$ for some integer $n$, so we include the case $t = 0$. Now we can give our necessary condition for $C_T$ to be finite.

**Corollary 3.2.** Suppose $C_T$ is finite. Then $g(T) = 1$.

**Proof.** Let $g = g(T)$, and observe that for any $t, u \in T$ there is $d \in \mathbb{Z}$ such that we have $c^{(l)}_k \equiv c^{(u)}_k + d \pmod{g}$ for all $k$. Hence (following Remark 1 from Section 2.3) $C_{(g \mid c^{(u)})} = C_{(g \mid c^{(u)})}$. In other words, the set $C_{(g \mid c^{(u)})}$ is the same for every $t \in T$. By Lemma 3.1 $C_{(g \mid c^{(u)})} \subseteq C_{(s \mid c^{(u)})}$, so $C_T$ contains $C_{(g \mid c^{(u)})}$. If $g \neq 1$ then $C_{(g \mid c^{(u)})}$ is infinite by Proposition 2.8, and hence so is $C_T$. 

3.2 The case where every $s^{(l)}$ is zero

In this subsection we assume that $s^{(l)} = 0$ for all $l \in T$. Perhaps surprisingly, this is the most complicated case.

We begin with a simple construction of core multipartitions.

**Lemma 3.3.** Suppose $c \in \mathbb{Z}^l$, let $m = \max\{c_1, \ldots, c_l\}$, and let $K = \{k \in \{1, \ldots, l\} \mid c_k = m\}$. For any $n \in \mathbb{N}$ define a multipartition $\lambda$ by

$$\lambda^{(k)} = \begin{cases} (n) & (k \in K) \\ \emptyset & (k \notin K). \end{cases}$$

Then $\lambda \in C_{(0 \mid c)}$.

**Proof.** The $(0 \mid c)$-content of $\lambda$ is $\{m|K|, (m + 1)|K|, \ldots, (m + n - 1)|K\}$. Suppose $\mu$ is a multipartition with this $(0 \mid c)$-content. Then $\mu^{(k)} = \emptyset$ for $k \notin K$, since $\mu$ has no nodes of residue less than $m$; for the same reason, $\mu_2^{(k)} = 0$ for $k \in K$. Furthermore, $\mu_1^{(k)} \leq n$ for $k \in K$, because $\mu$ has no nodes of residue greater than $m + n - 1$. The only possible $\mu$ satisfying these criteria is $\mu = \lambda$, so $\lambda$ is the unique multipartition with its $(0 \mid c)$-content.
Now we make a definition. Say that \( T \) satisfies condition X if there are \( t, u, v, w \in T \) and \( 1 \leq j, k \leq l \) such that
\[
   c_j^{(t)} \geq c_m^{(t)} \quad \text{for all } 1 \leq m \leq l, \quad c_j^{(u)} < c_m^{(u)} \quad \text{for some } 1 \leq m \leq l, \\
   c_k^{(v)} \leq c_m^{(v)} \quad \text{for all } 1 \leq m \leq l, \quad c_k^{(w)} > c_m^{(w)} \quad \text{for some } 1 \leq m \leq l.
\]

Another way of saying this is: the set of elements of \( \{1, \ldots, l\} \) on which \( c^{(t)} \) attains its maximum is not the same for all \( t \in T \), and the set of elements of \( \{1, \ldots, l\} \) on which \( c^{(t)} \) attains its minimum is not the same for all \( t \in T \).

Now we can state our main result for the case where every \( s^{(t)} \) equals 0.

**Theorem 3.4.** Suppose \( T = \{(0 \mid c^{(t)}) \mid t \in T\} \) is a set of \( l \)-multipartition data. Then \( C_T \) is finite if and only if \( g(T) = 1 \) and \( T \) satisfies condition X.

**Example.** Suppose \( T = \{((1 \mid 3, 0), (0 \mid 3, 0, 1))\} \). Then \( g(T) = 1 \) and \( T \) satisfies condition X. If \( \lambda \in C_T \), then by Proposition 2.3 \((\lambda^{(1)}, \lambda^{(2)}) \in C_{\{0 \mid 1, 3\}} \cap C_{\{0 \mid 3, 0\}} \). Lemma 3.5 below then tells us that \((\lambda^{(1)}, \lambda^{(2)}) \in C_{\{5 \mid 1, 3\}} \) and in particular \( \lambda^{(1)} \) and \( \lambda^{(2)} \) are both \( 5 \)-cores. Similarly, \((\lambda^{(2)}, \lambda^{(3)}) \in C_{\{4 \mid 3, 0\}} \), so \( \lambda^{(2)} \) and \( \lambda^{(3)} \) are both \( 4 \)-cores; since there are only finitely many \((4, 5)\)-cores, there are only finitely many possibilities for \( \lambda^{(2)} \). It follows from Proposition 2.6 that for a given \( 5 \)-core \( \lambda^{(2)} \) there are only finitely many bipartitions \((\lambda^{(1)}, \lambda^{(2)}) \) in \( C_{\{5 \mid 1, 3\}} \). So there are only finitely many possibilities for \( \lambda^{(1)} \). Similarly, there are only finitely many possibilities for \( \lambda^{(3)} \), and so \( C_T \) is finite.

In fact, we find that \( |C_T| = 30 \), with the largest tripartition in \( C_T \) being \(((1^3), (3^2, 1^3), (2^2))\).

One direction of the proof is easy.

**Proof of Theorem 3.4 (‘only if’ part).** By Corollary 3.2 \( C_T \) is infinite if \( g \neq 1 \). Now suppose \( T \) does not satisfy condition X. This means there is a set \( K \subseteq \{1, \ldots, l\} \) such that either \( c^{(t)} \) attains it maximum value precisely on \( K \) for every \( t \), or \( c^{(t)} \) attains its minimum value precisely on \( K \) for every \( t \). We assume we are in the first case (the other case is similar). By Lemma 3.3 the multipartition \( \lambda \) given by
\[
   \lambda^{(n)} = \begin{cases} (n) & \text{if } l \in K \\ \varnothing & \text{if } l \notin K \end{cases}
\]
lies in \( C_T \) for every \( n \), so \( C_T \) is infinite. \( \Box \)

Now we address the ‘if’ part of Theorem 3.4, which is considerably harder and requires some set-up. We start with two results on simultaneous core bipartitions.

**Lemma 3.5.** Suppose \( c_1, c_2, d_1, d_2 \in \mathbb{Z} \) with \( c_1 - c_2 \geq 0 > d_1 - d_2 \), and let \( a = c_1 - c_2 - d_1 + d_2 \). Then
\[
   C_{\{0 \mid c_1, c_2\}} \cap C_{\{0 \mid d_1, d_2\}} = C_{\{a \mid c_1, c_2\}}.
\]

**Proof.** Since \( c_1 - c_2 \equiv d_1 - d_2 \pmod{a} \), \( C_{\{a \mid c_1, c_2\}} = C_{\{a \mid d_1, d_2\}} \) is contained in both \( C_{\{0 \mid c_1, c_2\}} \) and \( C_{\{0 \mid d_1, d_2\}} \) by Lemma 3.1. So we just need to show that if \( \lambda \in C_{\{0 \mid c_1, c_2\}} \cap C_{\{0 \mid d_1, d_2\}} \) then \( \lambda \in C_{\{a \mid c_1, c_2\}} \). To see this, note that by Proposition 2.5
\[
   B_{c_1}^{\lambda(1)} \supseteq B_{c_2}^{\lambda(2)}, \quad B_{d_1}^{\lambda(1)} \subseteq B_{d_2}^{\lambda(2)}
\]
so that
\[ B_{c_1-c_2}^{(1)} \supseteq B^{(2)} \supseteq B_{d_1-d_2}^{(1)}. \]
The inequalities \( c_1 - c_2 \geq 0 > d_1 - d_2 \) mean that the residue of \( c_1 - c_2 \) modulo \( a \) is \( c_1 - c_2 \), so \( \lambda \in \mathcal{C}(a|c_1,c_2) \) by Proposition 2.6.

Note that the difference in the signs of \( c_1 - c_2 \) and \( d_1 - d_2 \) is crucial in Lemma 3.5. In the absence of this hypothesis, the components of a bipartition in \( \mathcal{C}(0|c_1,c_2) \cap \mathcal{C}(0|d_1,d_2) \) need not be \( a \)-cores. However, we have the following weaker result, which shows that we can bound the number of rim \( a \)-hooks of each component.

**Lemma 3.6.** Suppose \( c_1, c_2, d_1, d_2 \in \mathbb{Z} \) with \( c_1 - c_2 > d_1 - d_2 \geq 0 \), and let \( a = c_1 - c_2 - d_1 + d_2 \). If \( \lambda \in \mathcal{C}(0|c_1,c_2) \cap \mathcal{C}(0|d_1,d_2) \), then for \( k = 1, 2 \) the number of rim \( a \)-hooks of \( \lambda^{(k)} \) is at most \( d_1 - d_2 \).

**Proof.** We consider only \( \lambda^{(2)} \) (the proof for \( \lambda^{(1)} \) is similar). From Proposition 2.5 and the comments at the end of Section 2.4 we know that
\[ B_{c_1-c_2}^{(1)} = B^{(2)} \sqcup C, \quad B_{d_1-d_2}^{(1)} = B^{(2)} \sqcup D \]
for some sets \( C, D \) of sizes \( c_1 - c_2, d_1 - d_2 \) respectively. Hence
\[ \left\{ b-a \mid b \in B^{(2)} \sqcup C \right\} = B^{(2)} \sqcup D. \]
This means that if \( b \in B^{(2)} \) but \( b-a \notin B^{(2)} \), then \( b-a \in D \). Hence there are only \( |D| = d_1 - d_2 \) possible values for \( b \), so by Proposition 2.4 \( \lambda^{(2)} \) has at most \( d_1 - d_2 \) rim \( a \)-hooks.

Now we note the consequences for arbitrary simultaneous core multipartitions.

**Corollary 3.7.** Suppose \( \ell_j^{(t)} - c_k^{(t)} \geq 0 > c_j^{(u)} - c_k^{(u)} \) for some \( t, u \in T \) and \( 1 \leq j, k \leq l \). Let \( a = c_j^{(t)} - c_k^{(t)} - c_j^{(u)} + c_k^{(u)} \). If \( \lambda \in \mathcal{C}_T \), then \( \lambda^{(j)} \) and \( \lambda^{(k)} \) are \( a \)-cores.

**Proof.** By Proposition 2.3 the bipartition \( \lambda^{(j)}, \lambda^{(k)} \) is both an \((s^{(t)} | c_j^{(t)}, c_k^{(t)})\)-core and an \((s^{(u)} | c_j^{(u)}, c_k^{(u)})\)-core, and hence by Lemma 3.1 is both a \((0 | c_j^{(t)}, c_k^{(t)})\)-core and an \((0 | c_j^{(u)}, c_k^{(u)})\)-core. So by Lemma 3.5 \( \lambda^{(j)} \) is an \((a | c_j^{(u)}, c_k^{(u)})\)-core, and in particular \( \lambda^{(j)} \) and \( \lambda^{(k)} \) are \( a \)-cores.

**Corollary 3.8.** Suppose \( t, u \in T \) and \( 1 \leq j, k \leq l \), and let \( a = |c_j^{(t)} - c_k^{(t)} - c_j^{(u)} + c_k^{(u)}| \). If \( a > 0 \) and \( \lambda \in \mathcal{C}_T \), then the number of rim \( a \)-hooks of \( \lambda^{(j)} \) or \( \lambda^{(k)} \) is at least \[ \min \left\{ \frac{|c_j^{(t)} - c_k^{(t)}|}{|c_j^{(u)} - c_k^{(u)}|} \right\}. \]

**Proof.** By interchanging \( j \) and \( k \) or \( t \) and \( u \) if necessary, we can assume \( c_j^{(t)} - c_k^{(t)} > c_j^{(u)} - c_k^{(u)} \) and \( c_j^{(t)} - c_k^{(t)} \geq 0 \). If \( c_j^{(u)} - c_k^{(u)} < 0 \), then the result follows from Corollary 3.7, since then \( \lambda^{(j)} \) and \( \lambda^{(k)} \) are \( a \)-cores. So assume \( c_j^{(u)} - c_k^{(u)} \geq 0 \). Since \( \lambda^{(j)}, \lambda^{(k)} \) is both an \((s^{(t)} | c_j^{(t)}, c_k^{(t)})\)-core and an \((s^{(u)} | c_j^{(u)}, c_k^{(u)})\)-core, it is also a \((0 | c_j^{(t)}, c_k^{(t)})\)-core and an \((0 | c_j^{(u)}, c_k^{(u)})\)-core by Lemma 3.1, so the result follows from Lemma 3.6.

Now we need to consider bounding the number of rim \( a \)-hooks of a partition for different (coprime) values of \( a \). Given \( a > 0 \) and a partition \( \lambda \), let \( h_{k_1}(\lambda) \) denote the number of rim \( a \)-hooks of \( \lambda \). In particular, \( h_{k_1}(\lambda) \) is just the number of removable nodes of \( \lambda \).
Proposition 3.9. Suppose $P$ is a set of partitions, $A$ a set of coprime positive integers and $f : A \to \mathbb{N}$ a function such that $\text{hk}_A(\lambda) < f(a)$ for all $\lambda \in P$ and $a \in A$. Then there is $M \in \mathbb{N}$ such that $\text{hk}_P(\lambda) < M$ for all $\lambda \in P$.

Proof. We assume that $A$ is finite; if it is not, we can certainly replace $A$ with a finite subset whose elements are still coprime. Since the elements of $A$ are coprime, we can find $G \in \mathbb{N}$ such that any integer greater than $G$ can be written as a sum of elements of $A$. Suppose for a contradiction that $\text{hk}_P(\lambda)$ is unbounded for $\lambda \in P$; then by Proposition 2.4 we can find, for any $M \in \mathbb{N}$, a partition $\lambda \in P$ and integers $b_1 < \cdots < b_M \in B^\lambda$ such that $b_1 - 1, \ldots, b_M - 1 \notin B^\lambda$. Hence (letting $N = |M/G|$) we can find $c_1 < d_1 < c_2 < d_2 < \cdots < c_N < d_N$ such that for each $i$ we have $d_i - c_i > G$, $d_i \in B^\lambda$ and $c_i \notin B^\lambda$. But now by writing each $d_i - c_i$ as a sum of elements of $A$ and checking which integers between $c_i$ and $d_i$ lie in $B^\lambda$, we can find $c_i \leq e_i < f_i \leq d_i$ such that $f_i - e_i \in A$, $f_i \in B^\lambda$ and $e_i \notin B^\lambda$. Hence $\sum_{a \in A} \text{hk}_A(\lambda) \geq N$; taking $M$ such that $N > \sum_{a \in A} f(a)$ now gives a contradiction. □

Remark. In fact, it is easy to prove a more general result: without the assumption that the elements of $A$ are coprime, let $g$ be their greatest common divisor. Then one can show that the number of $g$-hooks of any partition in $P$ is bounded.

Now we need two more simple lemmas.

Lemma 3.10. Suppose $s, b \in \mathbb{N}$. Then there are only finitely many $s$-core partitions having no more than $b$ removable nodes.

Proof. An $s$-core $\lambda$ satisfies $\lambda_i - \lambda_{i+1} < s$ for every $i$, since otherwise there would be a rim $s$-hook contained in row $i$ of $[\lambda]$. So if $\lambda$ has no more than $b$ removable nodes, then $\lambda_1 \leq (s-1)b$. Similarly, the length of the first column of $\lambda$ is at most $(s-1)b$, so $|\lambda|$ is bounded. □

Lemma 3.11. If $\lambda \in C(s_{1,2})$ with $c_1 \leq c_2$, then $\lambda_1^{(1)} + c_1 \leq \lambda_1^{(2)} + c_2$.

Proof. By Proposition 2.5 and Lemma 3.1 we have $B_{s_{1,2}}^{(1)} \subseteq B_{s_{2,2}}^{(2)}$. In particular, $\lambda_1^{(1)} + c_1 \in B_{s_{2,2}}^{(2)}$, so there is $a \geq 1$ such that $\lambda_1^{(1)} - 1 + c_1 = \lambda_2^{(2)} - a + c_2$. But $\lambda_2^{(2)} - a \leq \lambda_1^{(1)} - 1$, which gives the result. □

Now we can proceed with the proof of the ‘if’ part of Theorem 3.4. Suppose $s^{(t)} = 0$ for all $t \in T$, and that $g(T) = 1$ and $T$ satisfies condition X. Say that $k \in \{1, \ldots, l\}$ is sometimes maximal if there is $t \in T$ such that $c_k^{(t)} \geq c_m^{(t)}$ for all $1 \leq m \leq l$, and sometimes minimal if there is $t \in T$ such that $c_k^{(t)} \leq c_m^{(t)}$ for all $1 \leq m \leq l$.

Lemma 3.12. Suppose $k \in \{1, \ldots, l\}$ is sometimes maximal or sometimes minimal. Then the set $\{ \lambda^{(k)} | \lambda \in C_T \}$ is finite.

Proof. Given the assumption that $s^{(t)} = 0$ for every $t \in T$, $g(T)$ is the greatest common divisor of the integers $c_k^{(t)} - c_j^{(t)} - c_k^{(u)} + c_j^{(u)}$ obtained as $j$ ranges over $\{1, \ldots, l\}$ and $t, u$ range over $T$; so by assumption these integers are coprime. By Corollary 3.8 if $|c_k^{(t)} - c_j^{(t)} - c_k^{(u)} + c_j^{(u)}| > 0$ then the number of $|c_k^{(t)} - c_j^{(t)} - c_k^{(u)} + c_j^{(u)}|$-hooks of $\lambda$ is bounded as $\lambda$ ranges over $C_T$. So if we let

$$A = \left\{ |c_k^{(t)} - c_j^{(t)} - c_k^{(u)} + c_j^{(u)}| \right\}_{t, u \in T, j \in \{1, \ldots, l\}} \setminus \{0\}$$

Matthew Fayers
and \( P = \{ \lambda^{(k)} \mid \lambda \in C_T \} \), then \( A \) and \( P \) satisfy the hypotheses of Proposition 3.9. So the number of 1-hooks (i.e. the number of removable nodes) of a partition in \( P \) is bounded, by \( b \) say.

Now Condition X together with the fact that \( k \) is sometimes maximal or sometimes minimal implies that there are \( t, u \in T \) and \( j \in \{ 1, \ldots, l \} \) such that either \( c_k^{(t)} - c_j^{(t)} \geq 0 > c_j^{(u)} - c_k^{(u)} \) or \( c_j^{(t)} - c_k^{(t)} \geq 0 > c_j^{(u)} - c_k^{(u)} \). If we let \( a = \left| c_k^{(t)} - c_j^{(t)} - c_k^{(u)} + c_j^{(u)} \right| \), then by Corollary 3.7 \( \lambda^{(k)} \) is an \( a \)-core for every \( \lambda \in C_T \). Since \( a > 0 \), Lemma 3.10 gives the result.

Now we can complete the proof.

**Proof of Theorem 3.4 (‘if’ part).** Suppose \( g(T) = 1 \) and \( T \) satisfies condition X. To show that \( C_T \) is finite, it suffices to show that for every \( k \in \{ 1, \ldots, l \} \) the set \( \{ \lambda^{(k)} \mid \lambda \in C_T \} \) is finite. We have proved this when \( k \) is sometimes maximal or sometimes minimal, so assume \( k \) is neither sometimes maximal nor sometimes minimal. The fact that \( k \) is not sometimes maximal means that there is \( j \) which is sometimes maximal and \( t \in T \) such that \( c_k^{(t)} \leq c_j^{(t)} \). If \( \lambda \in C_T \), then \((\lambda^{(k)}, \lambda^{(j)}) \in C_{(0, 0)^{(0)}, (0, 0)^{(t)}}\), so by Lemma 3.11 \( \lambda_k^{(k)} \leq \lambda_j^{(j)} \lambda_j^{(t)} - c_k^{(t)} \). Since by Lemma 3.12 there are only finitely many possible \( \lambda^{(j)} \), this means that \( \lambda_k^{(k)} \) is bounded for \( \lambda \in C_T \). Similarly (using the fact that \( k \) is not sometimes minimal) the first column of \( \lambda^{(k)} \) is bounded, so there are only finitely many possible \( \lambda^{(k)} \).

### 3.3 The case where \( s^{(t)} > 0 \) for some \( t \)

In this subsection we complete the analysis of when \( C_T \) is finite by considering the case where \( s^{(t)} > 0 \) for some \( t \in T \). The statement here is simpler.

**Theorem 3.13.** Suppose \( T = \{ (s^{(t)}, c^{(t)}) \mid t \in T \} \) is a set of \( l \)-multipartition data with \( s^{(t)} > 0 \) for at least one \( t \in T \). Then \( C_T \) is finite if and only if \( g(T) = 1 \).

We can deduce Theorem 3.13 fairly easily from Theorem 3.4. To begin with, we use Lemma 3.5 to express \( C(s, c) \) for any \( s, c \) as an intersection of sets \( C(0, d) \).

**Corollary 3.14.** Suppose \((s, c)\) is an \( l \)-multipartition datum with \( s > 0 \). Then

\[
C(s, c) = \bigcap_{d \in \mathbb{Z}^l} C(0, c + sd).
\]

**Proof.** For each \( d \in \mathbb{Z}^l \) we have \( C(s, c) = C(s, c + sd) \subseteq C(0, c + sd) \) by Lemma 3.1, so the left-hand side is contained in the right-hand side. For the opposite inclusion, suppose \( \lambda \in C(0, c + sd) \) for every \( d \in \mathbb{Z}^l \). Given \( 1 \leq j < k \leq l \), we can find \( d, e \in \mathbb{Z}^l \) such that \( 0 \leq (c_j + sd_j) - (c_k + sd_k) < s \) and \( e_j - e_k = d_j - d_k \). Then \((\lambda^{(j)}, \lambda^{(k)}) \in C(0, c_j + sd_j, c_k + sd_k) \cap C(0, c_j + sd_j, c_k + sd_k) = C(s, c_j, c_k)\) by Proposition 2.3 and Lemma 3.5. Since this is true for every \( j, k \), we have \( \lambda \in C(s, c) \) by Proposition 2.3.

**Remark.** In fact, one can write \( C(s, c) = \bigcap_{d \in M} C(0, c + sd) \) for a much smaller subset \( M \) of \( \mathbb{Z}^l \) — it is possible to take \(|M| = l\). But it is easier for us to take \( M \) to be the whole of \( \mathbb{Z}^l \) as in Corollary 3.14.
This yields the following.

**Proposition 3.15.** Suppose \( s(t) > 0 \) for at least one \( t \in T \). Then there is a set \( U = \{ (0 \mid c^{(u)}) \mid u \in U \} \) of \( l \)-multipartition data such that:

1. \( U \) satisfies condition X;
2. \( g(U) = g(T) \);
3. \( C_U = C_T \).

**Proof.** Define

\[
U = \left\{ (0 \mid c^{(t)} + s^{(t)}d) \mid t \in T, \ d \in \mathbb{Z}^l \right\}.
\]

Now we check the conditions in the proposition.

1. By assumption there is \( t \in T \) such that \( s(t) > 0 \). For any \( 1 \leq j < k \leq l \) we can easily find \( d, e \in \mathbb{Z}^l \) such that \( c_j^{(t)} + s^{(t)}d_j > c_k^{(t)} + s^{(t)}d_k \) and \( c_j^{(t)} + s^{(t)}e_j < c_k^{(t)} + s^{(t)}e_k \). Doing this for any \( j, k \) is certainly enough to guarantee condition X for \( U \).
2. By definition \( g(T) \) is the greatest common divisor of the integers in the set

\[
\left\{ s^{(t)} \mid t \in T \right\} \cap \left\{ c_i^{(t)} - c_j^{(t)} - c^{(u)}_i + c^{(u)}_j \mid t, u \in T, \ 1 \leq i, j \leq l \right\},
\]

while \( g(U) \) is the greatest common divisor of the integers in the set

\[
\left\{ c_i^{(t)} - c_j^{(t)} - c^{(u)}_i + c^{(u)}_j + s^{(t)}a + bs^{(u)} \mid t, u \in T, \ 1 \leq i, j \leq l, \ a, b \in \mathbb{Z} \right\}.
\]

It is easy to see that these greatest common divisors are the same.
3. This follows from Corollary 3.14. \( \square \)

**Proof of Theorem 3.13.** The ‘only if’ part is Corollary 3.2. For the ‘if’ part, suppose \( g(T) = 1 \), and let \( U \) be as in Proposition 3.15. Then by Theorem 3.4 \( C_T = C_U \) is finite. \( \square \)

## 4 Enumeration of simultaneous core multipartitions

An early success in the study of simultaneous core partitions was Anderson’s Theorem [An, Theorems 1 & 3] that when \( s \) and \( t \) are coprime, the number of \( (s, t) \)-cores is the rational Catalan number \( \frac{1}{s + 1} \left( \frac{s + t}{s} \right) \). Extending this to enumeration of partitions in \( C_{s_1} \cap \cdots \cap C_{s_r} \) for coprime integers \( s_1, \ldots, s_r \) with \( r \geq 3 \) seems to be much more difficult, although various special cases have been addressed in the recent literature [HN, Am, AL, W, X].

Naturally, one can extend these enumerative questions to simultaneous core multipartitions: in particular, given a set \( T \) of \( l \)-multipartition data such that \( C_T \) is finite (as determined by Theorems 3.4 and 3.13), what is \( |C_T| \)? This question seems to be very hard to answer in general; the proofs of Theorems 3.4 and 3.13 do not give anything like an efficient algorithm for calculating \( C_T \), so it is difficult even to gather data. In this section we address the very simplest case, where \( l = |T| = 2 \). Even here the enumeration question is difficult to answer, and we restrict to two particular subcases.
If \( l = |T| = 2 \), we can assume (in view of Remark 1 from Section 2.3) that
\[
T = \{(s \mid 0, a), (t \mid 0, b)\}
\]
with \( s, t \in \mathbb{N} \cup \{0\} \) and \( a, b \in \mathbb{Z} \). Moreover, if \( s > 0 \) then we can take \( 0 \leq a < s \), and similarly for \( t \) and \( b \).

### 4.1 The case where \( s \) divides \( t \)

In this subsection we take \( T \) as above with \( s \) dividing \( t \). We start with the case \( s = t = 0 \). In this case \( g(T) = |a - b| \), so we need \( |a - b| = 1 \) in order to have \( C_T \) finite. But we also need \( T \) to satisfy condition \( \lambda \), which means that \( a \) or \( b \) equals 0. Now we have the following result.

**Proposition 4.1.** Suppose \( T = \{(0 \mid 0, a), (0 \mid 0, b)\} \), with \( \{|a|, |b|\} = \{0, 1\} \). Then \( |C_T| = 1 \).

**Proof.** We assume \( a = 0 \) and \( b = 1 \) (the other cases follow symmetrically). Suppose \((\lambda, \mu)\) is a bipartition lying in \( C_T \); we will show that \( \lambda = \mu = \emptyset \). By Proposition 2.5 the fact that \((\lambda, \mu) \in C_{(0 \mid 0, 0)} \) says that \( B^\lambda = B^\mu \); since a partition can be recovered from its beta-set, we obtain \( \lambda = \mu \). Now the fact that \((\lambda, \lambda) \in C_{(0 \mid 0, 1)} \) gives \( B^\lambda \subseteq B^\lambda_1 \); following the comments at the end of Section 2.4 this means that \( B^\lambda_1 = B^\lambda \cup \{b\} \) for some integer \( b \). In fact it is easy to see that \( b \) must equal \( \lambda_1 \) (since this lies in \( B^\lambda_1 \) and is larger than the largest element \( \lambda_1 - 1 \) of \( B^\lambda \)). Hence we have \( B^\lambda_1 \setminus \{\lambda_1\} = B^\lambda \); writing the elements of these sets in decreasing order, we obtain
\[
\lambda_2 - 1 = \lambda_1 - 1, \quad \lambda_3 - 2 = \lambda_2 - 2, \quad \lambda_4 - 3 = \lambda_3 - 3, \ldots
\]
so that \( \lambda_1 = \lambda_2 = \lambda_3 = \ldots \), and therefore \( \lambda = \emptyset \). \( \Box \)

Now we consider the case where \( s, t > 0 \). We will deduce our main result here as a special case of a more general result. So we do not assume that \( s \) divides \( t \), and we let \( g \) be the greatest common divisor of \( s \) and \( t \) throughout this section. We will restrict attention to bipartitions \((\lambda, \mu)\) for which both \( \lambda, \mu \) are \( g \)-cores. Let \( C^2_s \) denote the set of such bipartitions.

Let \( U^{s,a}_g \) denote the set of all tuples \( u = (u_i \mid i \in \mathbb{Z}/g\mathbb{Z}) \) of integers with \( \sum_i u_i = a \) and \( 0 \leq u_i \leq s/g \) for each \( i \in \mathbb{Z}/g\mathbb{Z} \). By a simple application of the Inclusion–Exclusion Principle,
\[
|U^{s,a}_g| = \sum_{d \geq 0} (-1)^d \binom{s}{d} \binom{a + s - 1 - j(1 + s/g)}{g - 1}.
\]
Now we can state our main theorem in this section.

**Theorem 4.2.** Suppose \( 0 \leq a < s \) and \( 0 \leq b < t \). Let \( g = \text{gcd}(s, t) \), and assume \( g \) and \( a - b \) are coprime. Then
\[
|C_{(s \mid 0, a)} \cap C_{(t \mid 0, b)} \cap C^2_g| = \frac{1}{g} |U^{s,a}_g| |U^{t,b}_g|.
\]
In particular, if \( s \) divides \( t \), then
\[
|C_{(s \mid 0, a)} \cap C_{(t \mid 0, b)}| = \frac{1}{s} \binom{s}{a} |U^{t,b}_s|.
\]
To prove Theorem 4.2, we use a slightly different version of Proposition 2.6 to characterise core bipartitions. Suppose $\lambda$ is an $s$-core and $i \in \mathbb{Z}/s\mathbb{Z}$. Let $\diamondsuit_i(\lambda)$ be the smallest element of $i$ not contained in $B^\lambda$. The set $\diamondsuit_s(\lambda) = \{ \diamondsuit_i(\lambda) \mid i \in \mathbb{Z}/s\mathbb{Z} \}$ is referred to as the $s$-set of $\lambda$; these sets were studied extensively in [F2, F3, F4]. Observe that $\diamondsuit_s(\lambda)$ is a set of $s$ integers which are pairwise incongruent modulo $s$ and sum to $\binom{s}{2}$. Conversely, any such set of integers is the $s$-set of a unique $s$-core.

Now we can give a different version of Proposition 2.6 (in fact, this is much closer to the original version of this result in [F1]).

**Proposition 4.3.** Suppose $\lambda, \mu \in C_s$ and $0 \leq a < s$. Then $(\lambda, \mu) \in C_{(s \mid 0, a)}$ if and only if

\[
\diamondsuit_i(\mu) + a = \{ \diamondsuit_{i+a}(\lambda), \diamondsuit_{i+a}(\lambda) + s \}.
\]

for each $i \in \mathbb{Z}/s\mathbb{Z}$.

In order to use Proposition 4.3 to prove Theorem 4.2, we want to consider bipartitions $(\lambda, \mu) \in C_{(s \mid 0, a)}$ with $\lambda, \mu \in C_s$. Proposition 4.3 tells us exactly how to construct these: by Proposition 2.6, $(\lambda, \mu) \in C_{(s \mid 0, a)}$ if and only if $\diamondsuit_i(\mu) + a = \diamondsuit_{i+a}(\lambda)$ equals either $s$ or $0$ for each $i$. If this is the case, then since $\sum_i \diamondsuit_i(\lambda) = \sum_i \diamondsuit_i(\mu)$, the integer $\diamondsuit_i(\mu) + a = \diamondsuit_{i+a}(\lambda)$ equals $s$ for exactly $a$ values of $i$. Since $\lambda$ is a $g$-core and $g$ divides $s$, it is easy to see that

\[
\diamondsuit_s(\lambda) = \{ \diamondsuit_s(\lambda) + kg \mid i \in \mathbb{Z}/g\mathbb{Z}, 0 \leq k < g \}
\]

and similarly for $\mu$. As a consequence, if $(\lambda, \mu) \in C_{(s \mid 0, a)} \cap C^2_s$, then there is a tuple $u \in U^s_{\mathbb{Z}}$ such that $\diamondsuit_i(\mu) + a = \diamondsuit_{i+a}(\lambda) + gu$, for each $i \in \mathbb{Z}/g\mathbb{Z}$. We define $\sigma(\lambda, \mu) = u$, giving a function

\[
\sigma : C_{(s \mid 0, a)} \cap C^2_s \rightarrow U^s_{\mathbb{Z}}.
\]

Replacing $s, a$ with $t, b$, we get another function

\[
\tau : C_{(t \mid 0, b)} \cap C^2_s \rightarrow U^{t,b}_{\mathbb{Z}}.
\]

**Proof of Theorem 4.2.** We want to consider the images of the maps $\sigma, \tau$ defined above, and we need some more notation. For any tuple $u = (u_i \mid i \in \mathbb{Z}/g\mathbb{Z})$ and $c \in \mathbb{Z}/g\mathbb{Z}$ define the tuple $u(+c)$ by $u(+c)_i = u_{i+c}$ for each $i \in \mathbb{Z}/g\mathbb{Z}$.

To prove the theorem we will prove the following claim: given $u \in U^s_{\mathbb{Z}}$ and $v \in U^{t,b}_{\mathbb{Z}}$, there are unique $(\lambda, \mu) \in C_{(s \mid 0, a)} \cap C_{(t \mid 0, b)} \cap C^2_s$ and $c \in \mathbb{Z}/s\mathbb{Z}$ such that $\sigma(\lambda, \mu) = u(+c)$ and $\tau(\lambda, \mu) = v(+c)$.

Our first aim is to find integers $x_i, y_i$ for $i \in \mathbb{Z}/g\mathbb{Z}$ such that

\[
y_i = x_{i+a} - a + gu_i = x_{i+b} - b + gv_i
\]

for all $i$. In fact, this is straightforward: we just fix $k \in \mathbb{Z}$ and set

\[
x_{d(b-a)+gZ} = k + d(b-a) + g \sum_{j=0}^{d-1} u_{j(b-a)+gZ} - g \sum_{j=1}^{d} v_{j(b-a)+gZ}
\]

\[
y_{d(b-a)-a+gZ} = k + d(b-a) - a + g \sum_{j=0}^{d} u_{j(b-a)+gZ} - g \sum_{j=1}^{d} v_{j(b-a)+gZ}
\]

for all $0 \leq d < g$. Since $b - a$ and $g$ are coprime, this uniquely defines $x_i$ and $y_i$ for every \( i \in \mathbb{Z}/g\mathbb{Z} \), and it is easy to see that (\(*\)) is satisfied. Moreover, apart from the choice of $k$, these are the unique integers $x_i, y_i$ satisfying (\(*\)) once $x_0 + g\mathbb{Z} = k$ is chosen, (\(*\)) forces the choice of \( -a + g\mathbb{Z}, x_b - a + g\mathbb{Z}, y_b - 2a + g\mathbb{Z}, x_2b - 2a + g\mathbb{Z}, \ldots \) so that $x_i$ and $y_i$ are forced for every $i$.

Now observe that the integers $x_i$ are pairwise incongruent modulo $g$, so in particular sum to \( (\frac{g}{2}) \) modulo $g$. Changing $k$ by 1 changes this sum by $g$, and therefore there is a unique choice of $k$ (which we fix henceforth) such that $\sum_i x_i = (\frac{g}{2})$. This also gives $\sum_i y_i = (\frac{g}{2})$, so $\{ x_i \mid i \in \mathbb{Z}/g\mathbb{Z} \}$ and $\{ y_i \mid i \in \mathbb{Z}/g\mathbb{Z} \}$ are the $g$-sets of $g$-cores $\lambda$ and $\mu$ respectively. Since $x_i \in i + k$, we have $\diamondsuit_i(\lambda) = x_{i-k}$, and similarly $\diamondsuit_i(\mu) = y_{i-k}$, for each $i \in \mathbb{Z}/g\mathbb{Z}$, and hence

$$\diamondsuit_i(\mu) + a - \diamondsuit_{i+a}(\lambda) = y_{i-k} - x_{i+a-k} + a = g u_{i+k},$$

so that $(\lambda, \mu) \in C_{(s \mid 0, a)}$ with $\sigma(\lambda, \mu) = u(+c)$, where $c = k + g\mathbb{Z}$. Similarly $(\lambda, \mu) \in C_{(t \mid 0, b)}$ with $\tau(\lambda, \mu) = v(+c)$, so we have the required $\lambda, \mu, c$. Moreover, the integers $x_i, y_i$ can be recovered from $\lambda, \mu, c$, so (by the statement above about the uniqueness of $x_i, y_i$) we have uniqueness for $\lambda, \mu, c$.

As a consequence of this claim, we find that $|C_{(s \mid 0, a)} \cap C_{(t \mid 0, b)} \cap C_{g \mathbb{Z}}|$ equals $\frac{1}{g}$ times the number of choices of $u, v$. $u$ can be chosen in $|U_{s, a}^U|$ ways, and $v$ in $|U_{t, b}^U|$ ways, giving the result.

For the special case where $s$ divides $t$, we have $g = s$, so that $|U_{s, a}^U| = (\frac{s}{a})$. Furthermore, $C_{(s \mid 0, a)} \subseteq C_{g \mathbb{Z}}$ by Lemma 2.2, and the result follows. \hfill \Box

**Example.** Take $s = 3$, $t = 9$, $a = 1$ and $b = 5$. The twelve bipartitions $(\lambda, \mu) \in C_{(3 \mid 0, 1)} \cap C_{(9 \mid 0, 5)}$ are given by the following table, where we give $\diamondsuit_3(\lambda), \diamondsuit_3(\mu), \sigma(\lambda, \mu), \tau(\lambda, \mu)$, writing each $\mathbb{Z}/3\mathbb{Z}$-tuple $u$ in the form $(u_{0+3\mathbb{Z}}, u_{1+3\mathbb{Z}}, u_{2+3\mathbb{Z}})$. We see that up to simultaneous cyclic permutation, each pair in $U_{3, 1}^3 \times U_{5, 5}^5$ occurs once as $(\sigma(\lambda, \mu), \tau(\lambda, \mu))$.

</tbody>
</table>

**Remark.** It remains to consider the case where $s > 0$ and $t = 0$. We deal with this case as a limiting case of Theorem 4.2. So take $s, t, a, b$ with $t = ns$ for $n \in \mathbb{N}$. For large $n$ (in fact, for $n \gg b$), the value of $|U_{s, b}^U|$ stabilises as \( (\frac{b^{s+1} - 1}{s-1}) \). In addition, one can see from the proof of Theorem 4.2 that the set $C_{(s \mid 0, a)} \cap C_{(ns \mid 0, b)}$ stabilises; call this limiting set $\mathcal{C}$. We claim that $C_{(s \mid 0, a)} \cap C_{(0 \mid 0, b)} = \mathcal{C}$. By Lemma 3.1, $C_{(ns \mid 0, b)} \subseteq C_{(0 \mid 0, b)}$ for every $n$, so we have $\mathcal{C} \subseteq C_{(s \mid 0, a)} \cap C_{(0 \mid 0, b)}$. On the other hand, given a bipartition $(\lambda, \mu)$ and given $N$ sufficiently large relative to $(\lambda, \mu)$, we have $(\lambda, \mu) \in C_{(N \mid 0, b)}$ if and only if $(\lambda, \mu) \in C_{(0 \mid 0, b)}$: we just take $N$ large enough that
any two nodes which can occur as nodes of bipartitions of size $|\lambda| + |\mu|$ have the same $(N | 0, b)$-residue if and only if they have the same $(0 | 0, b)$-residue. So if $(\lambda, \mu) \notin C$, then for sufficiently large $n$ $(\lambda, \mu) \notin C_{(s | 0, a)} \cap C_{(t | 0, b)}$, so that $(\lambda, \mu) \notin C_{(s | 0, a)} \cap C_{(0 | 0, b)}$. Hence $C_{(s | 0, a)} \cap C_{(0 | 0, b)} = C$ as required.

So we deduce that

$$|C_{(s | 0, a)} \cap C_{(0 | 0, b)}| = \frac{1}{s} \binom{s}{a} \binom{b + s - 1}{s - 1}.$$  

4.2 The case $0 \leq a = b < s, t$

Now we consider the case where the residue of $a$ modulo $s$ is the same as the residue of $b$ modulo $t$. In this case, we may assume that $0 \leq a = b < s, t$.

**Theorem 4.4.** Suppose $0 \leq a < s \leq t$, and that $s$ and $t$ are coprime. Then

$$|C_{(s | 0, a)} \cap C_{(t | 0, a)}| = \frac{(s + t - a - 1)!}{a!(s - a)!(t - a)!}.$$  

In order to prove Theorem 4.4, we recall the $(s, t)$-lattice used in Anderson’s proof of her theorem. This is a diagram of $\mathbb{Z}^2$, with the point $(x, y)$ replaced by $sx + ty$. For example, part of the $(3, 5)$-lattice is drawn as follows.

| 0 3 6 9 12 15 18 21 24 27 30 |
|---|---|---|---|---|---|---|---|---|---|---|
| -5 -2 1 4 7 10 13 16 19 22 25 |
| -10 -7 -4 -1 2 5 8 11 14 17 20 |
| -15 -12 -9 -6 -3 0 3 6 9 12 15 |
| -20 -17 -14 -11 -8 -5 -2 1 4 7 10 |
| -25 -22 -19 -16 -13 -10 -7 -4 -1 2 5 |
| -30 -27 -24 -21 -18 -15 -12 -9 -6 -3 0 |

Note that the $(s, t)$-lattice is periodic: it is unchanged under translations by multiples of the vector $(t, -s)$. To construct the $(s, t)$-diagram (sometimes called the $(s, t)$-abacus diagram) of a partition $\lambda$, one simply colours or circles the integers lying in $B^\lambda$. By Proposition 2.4, the condition that $\lambda$ is an $(s, t)$-core is then simply that each coloured position has coloured positions
Simultaneous core multipartitions

both below and to the left. Part of the (3, 5)-diagram of the (3, 5)-core (1) is as follows.

```
  0  3  6  9 12 15 18 21 24 27 30
- 5 -2  1  4  7 10 13 16 19 22 25
-10 -7 -4 -1  2  5  8 11 14 17 20
-15 -12 -9 -6 -3  0  3  6  9 12 15
-20 -17 -14 -11 -8 -5 -2  1  4  7 10
-25 -22 -19 -16 -13 -10 -7 -4 -1  2  5
-30 -27 -24 -21 -18 -15 -12 -9 -6 -3  0
```

Now consider the boundary between the coloured and uncoloured parts of the diagram. The condition that \( \lambda \) is an \((s, t)\)-core means that this path consists only of steps to the right and steps down. Moreover, it is periodic, with each period consisting of \( t \) steps to the right and \( s \) steps down. We can encode this boundary path by writing down one period; of course, any cyclic permutation of this period will encode the same periodic boundary path. For example, we can encode the boundary path in the diagram above by (any cyclic permutation of) the sequence DRDRDRDRRR.

Conversely, any cyclic sequence comprising \( s \) Rs and \( t \)Ds yields the \((s, t)\)-diagram of an \((s, t)\)-core: if we draw the corresponding periodic path in the \((s, t)\)-lattice, then the set of integers below and to the left of the path is the shifted beta-set of an \((s, t)\)-core. Translating the path to a different position just changes the shift of the beta-set, without changing the partition.

As a consequence, we find that the number of \((s, t)\)-cores equals the number of arrangements of \( s \) Rs and \( t \)Ds modulo cyclic shifts, which yields Anderson’s Theorem.

Now we extend these ideas to the setting of Theorem 4.4. Suppose we have \( 0 \leq a < s, t \), and that \((\lambda, \mu) \in C_{(s, a)} \cap C_{(t, a)}\). Consider the shifted beta-set \( B^{\mu}_{a} \). By Proposition 4.3, this is obtained from \( B^{\lambda}_{a} \) by adding \( a \) integers \( x_{1}, \ldots, x_{a} \), with \( x_{j} - s \in B^{\lambda}_{a} \) for each \( j \). The same applies with \( t \) in place of \( s \). So drawing the \( a \)-shifted \((s, t)\)-diagram of \( \mu \) (i.e. colouring the elements of \( B^{\mu}_{a} \)) amounts to taking the \((s, t)\)-diagram of \( \lambda \) and additionally colouring \( a \) integers each of which has coloured integers both immediately below and immediately to the left. For example, take \((s, t, a) = (3, 5, 2)\), and \((\lambda, \mu) = (\{(1), (2)\})\). Combining the \((3, 5)\)-diagram of \( \lambda \) and the \(2\)-shifted \((3, 5)\)-diagram of \( \mu \), we get the following picture (in which we use a lighter colour...
for the additional positions coloured in $\mu$.

</table>

We can encode this diagram by writing a B for each light-coloured box, with a sequence of Rs and Ds representing the path joining each box to the next. We see that we obtain a periodic sequence, with each period comprising a Bs, $s - a$ Ds, and $t - a$ Rs. Conversely, any cyclic sequence of these symbols yields a bipartition $p$ sequence, with each period comprising $a$ Rs, modulo cyclic shifts. Counting these is a straightforward combinatorial exercise: disregarding cyclic shifts there are $(s + t - a)!/a!(s - a)!(t - a)!$ such sequences. None of these is fixed by any non-trivial cyclic shift, since the integers $a, s - a, t - a$ are coprime. So the final count is $(s + t - a - 1)!/a!(s - a)!(t - a)!$.

### 4.3 Extending Armstrong’s Conjecture

A recent exciting development in the theory of $(s, t)$-cores is Johnson’s proof [J] of Armstrong’s Conjecture, which says that the average size of an $(s, t)$-core is $\frac{1}{24}(s - 1)(t - 1)(s + t + 1)$. Of course, one can ask for the average size of a simultaneous core multipartition. Here we comment briefly on analogues of Armstrong’s Conjecture for the two special cases mentioned in Sections 4.1 and 4.2.

First consider the case $s = t$; this is a (more) special case of the results in Section 4.1, where we have $|C_{(s \mid 0, a)} \cap C_{(s \mid 0, b)}| = \frac{1}{s} \left( \begin{array}{c} s \\ a \\ \end{array} \right) \left( \begin{array}{c} s \\ b \\ \end{array} \right)$, and we make the following conjecture.

**Conjecture 4.5.** Suppose $0 \leq a, b < s$, and that $s$ and $a - b$ are coprime. Then the average size of a bipartition in $C_{(s \mid 0, a)} \cap C_{(s \mid 0, b)}$ is

$$\frac{(s + 1)(a(s - a) + b(s - b) + 1 - s)}{12}.$$

**Example.** Take $s = 5$, $a = 1$ and $b = 3$. Then $|C_{(5 \mid 0, 1)} \cap C_{(5 \mid 0, 3)}| = \frac{1}{5} \left( \begin{array}{c} 5 \\ 1 \\ \end{array} \right) \left( \begin{array}{c} 5 \\ 3 \\ \end{array} \right) = 10$. The Young diagrams of the ten bicores in $C_{(5 \mid 0, 1)} \cap C_{(5 \mid 0, 3)}$ are as follows.

```
∅ ∅  ∅  ∅  ∅ ∅ ∅ ∅ ¨ ∅
```

```
```
```
```
```
```
```
```
```
```
```
Simultaneous core multipartitions

These bipartitions have an average size of 3, as predicted by Conjecture 4.5.

**Remark.** In fact, Armstrong’s Conjecture appears in disguise as a special case of Conjecture 4.5. Suppose \( a = 0 \). Proposition 2.6 shows that \((\lambda, \mu) \in \mathcal{C}_{s|0,0} \) if and only if \( \lambda = \mu \) and \( \lambda \) is an \( s \)-core. Applying Proposition 2.6 again, we find that \((\lambda, \lambda) \in \mathcal{C}_{s|0,b} \) if and only if \( \lambda \) is both a \( b \)-core and an \((s - b)\)-core. So in this case, \( \mathcal{C}_T \) is simply the set of bipartitions \((\lambda, \lambda)\), where \( \lambda \) is a \((b, s - b)\)-core. (Note that such a partition is automatically an \( s \)-core.) So when \( a = 0 \), Conjecture 4.5 is equivalent to Armstrong’s Conjecture.

Now consider the case \( a = b \) addressed in Section 4.2. Here we make the following conjecture.

**Conjecture 4.6.** Suppose \( 0 \leq a \). Then there is a polynomial function \( f_a(s, t) \) of degree 3 (but of degree 2 in each of \( s, t \)) with integer coefficients such that for \( s, t \) coprime integers greater than \( a \), the average size of a bipartition in \( \mathcal{C}_{s|0,a} \cap \mathcal{C}_{t|0,a} \) equals \( f_a(s, t)/12 \).

In particular, \( f_0(s, t) = (s - 1)(t - 1)(s + t + 1) \) and \( f_1(s, t) = (s - 1)(t - 1)(s + t - 1) \).

The case \( a = 0 \) is just Armstrong’s Conjecture, since \( \mathcal{C}_{s|0,0} \cap \mathcal{C}_{t|0,0} \) is the set of bipartitions \((\lambda, \lambda)\) with \( \lambda \) an \((s, t)\)-core.

**Example.** Take \( s = 3, t = 4 \) and \( a = 1 \). Then \(|\mathcal{C}_{3|0,1} \cap \mathcal{C}_{4|0,3}| = \frac{5!}{12} = 10\). The Young diagrams of the ten bicores in \( \mathcal{C}_{3|0,1} \cap \mathcal{C}_{4|0,3} \) are as follows.

\[
\begin{array}{cccccc}
\emptyset & \emptyset & \emptyset & \emptyset & \emptyset & \emptyset \\
\emptyset & \emptyset & \emptyset & \emptyset & \emptyset & \emptyset \\
\emptyset & \emptyset & \emptyset & \emptyset & \emptyset & \emptyset \\
\emptyset & \emptyset & \emptyset & \emptyset & \emptyset & \emptyset \\
\emptyset & \emptyset & \emptyset & \emptyset & \emptyset & \emptyset \\
\emptyset & \emptyset & \emptyset & \emptyset & \emptyset & \emptyset \\
\end{array}
\]

These bipartitions have an average size of 3, as predicted by Conjecture 4.6.

Johnson’s proof of Armstrong’s Conjecture relies on a geometric realisation of the set of \((s, t)\)-cores, using Ehrhart theory. We hope to extend these ideas to core multipartitions in a future paper.
